

Review of HWRF-base Ensemble Prediction System 2014-2018 Atlantic Storms

Zhan Zhang

EMC/NCEP/NWS/NOAA, College Park, MD 20740

Outline

- Configuration of HWRF-base Ensemble Prediction System (HWRF-EPS)
- Methodology
- Statistical Features of HWRF-EPS
- Mean Vmax probability produced by HWRF-EPS
- Verification and Evaluation of HWRF-EPS
- Concluding Remarks

HWRF ensemble Configuration

- Use then operational deterministic HWRF model except for
 - Less horizontal resolution: 14.5/4.5/1.5km vs. 18/6/2km (27/9/3km, before 2018)
 - Less vertical resolution: L75 vs. L61 (L43 before 2018)
 - No GSI due to lack of GDAS data;
- IC/BC Perturbations (large scale): 20 member GEFS, 0.5x0.5 degree GRIB2 (1x1deg. Before 2018)
- Model Physics Perturbations (vortex scale):
 - Stochastic Convective Trigger Perturbations in SAS: - 50hPa to + 50hPa white noise ;
 - Stochastic boundary layer height perturbations in PBL scheme, -20% to +20%;
 - Stochastic Cd perturbation;
- Situation-appropriate perturbations to the initial time position and intensity in TC Vital.
- Initial ocean SST perturbations (Xiao Hui & Ryan Torn, added in 2017)
 - Climatological (2012-2016), GFS surface analysis
 - Remove climatological mean, scale to 0.5K standard deviation.
 - Mix the initial SST perturbation downward into upper ocean (150 m).
- Use values of coac and codamp for 2km resolution (2018)

Methodology

Posterior Analysis on Track/Intensity Forecasts

- The best track information is available at all forecast hours
- Select one ensemble member that is closest to the observed position to represent ensemble track forecasts, MPTE: Minimum Potential Track Error
- Select one ensemble member that is closest to the observed Vmax to represent ensemble intensity forecasts, MPIE: Minimum Potential Intensity Error
- Mean Probability Density Function (PDF) from HWRF-based Ensemble System
- Vmax distributions from each individual ensemble member (unsorted), and re-group member (sorted)
- Analysis Vmax distributions for unsorted and sorted ensembles

Post-processing on HWRF-EPS

- The best track information is available at forecast 12h
- Select a subset of ensemble members that both track and intensity forecasts at 12h are close to the best track, average over the subset
- Weight between track and intensity sets 0.5
- Subset of 12 members (out of 20) is found to provide best results, I₁₂₉: HWRF ensemble track and intensity forecasts provided 12h later

Track/Intensity Verification

- All ensemble member average vs. un-perturbed control member and MPTE/MPIE
- Forecast skill improvement of sub-setting method over all ensemble member mean

Potential applications of MPTE/MPIE:

1. Verify/validate ensemble system by checking equal chance of being best forecast for each individual ensemble member
2. Investigate best forecast member to understand model physics;
3. Study the predictability of current dynamic model, intrinsic predictability limit.

Dataset

2014-2018 Atlantic storms:

Fcst hrs	000	024	048	072	096	120
No. of Cycles	897	816	721	634	542	452

HW01-HW20: Perturbed Ensemble Members

HW00: Un-perturbed Control run

MPTE: Minimum Potential Track Error

MPIE: Minimum Potential Intensity Error

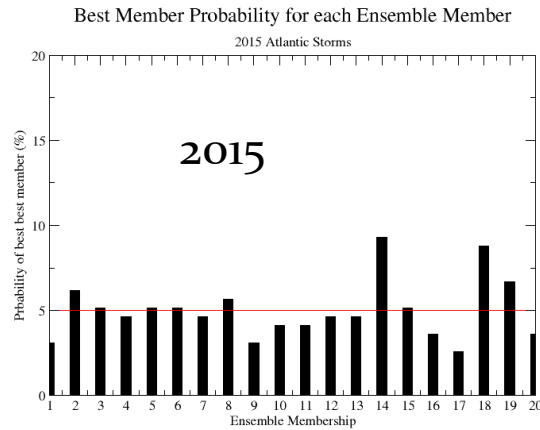

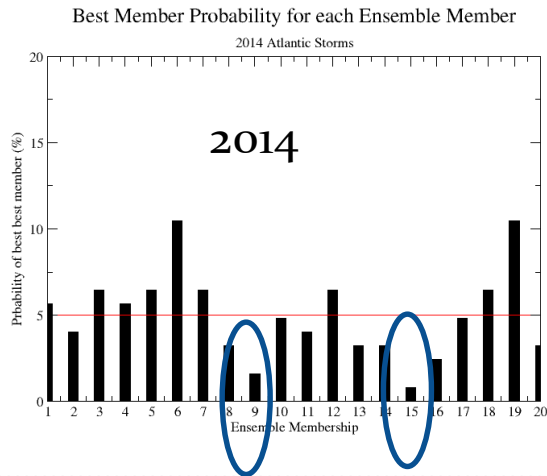

HWRF: Operational HWRF

I129: Sub-setting track/intensity forecasts

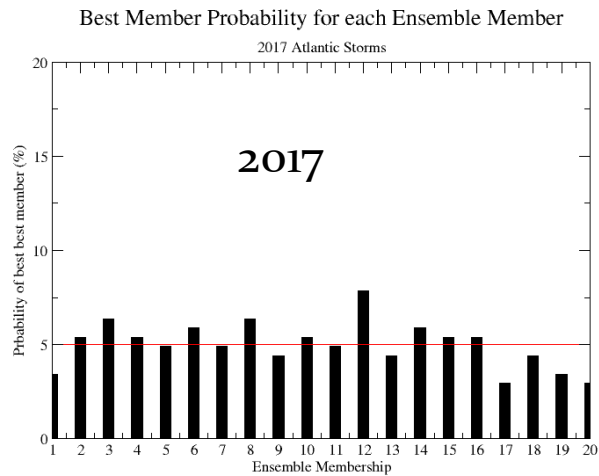

Statistical Features of HWRF-EPS

Statistic Features of HWRF-based Ensemble

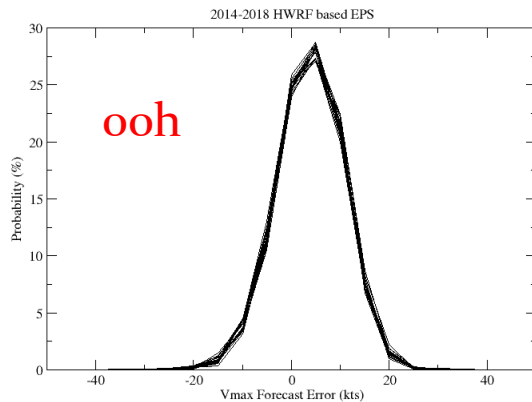

1/20 or 5% line

Vmax Distributions from Each individual Ensemble Members

Averaged over Atlantic Storms from 2014-2018

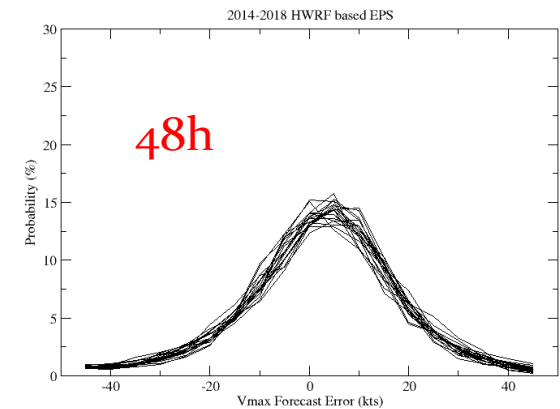

Vamx Error Probability at 000hr for Unsorted Ensemble

Vmax Error Probability at 024hr for Unsorted Ensemble

Vamx Error Probability at 048hr for Unsorted Ensemble

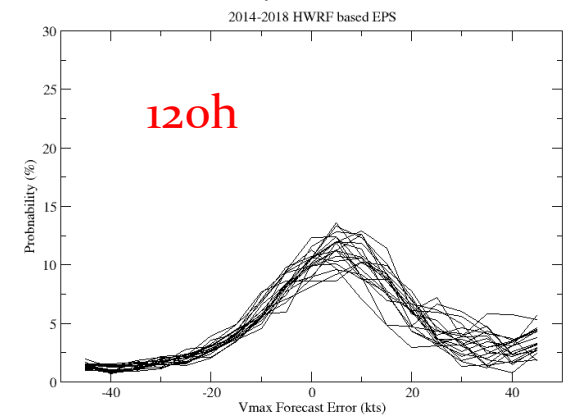

Vmax Error Probability at 072hr for Unsorted Ensemble

Vmax Error Probability at 096hr for Unsorted Ensemble

Vmax Error Probability at 120hr for Unsorted Ensemble

Vmax Forecast Error vs Ensemble Spread

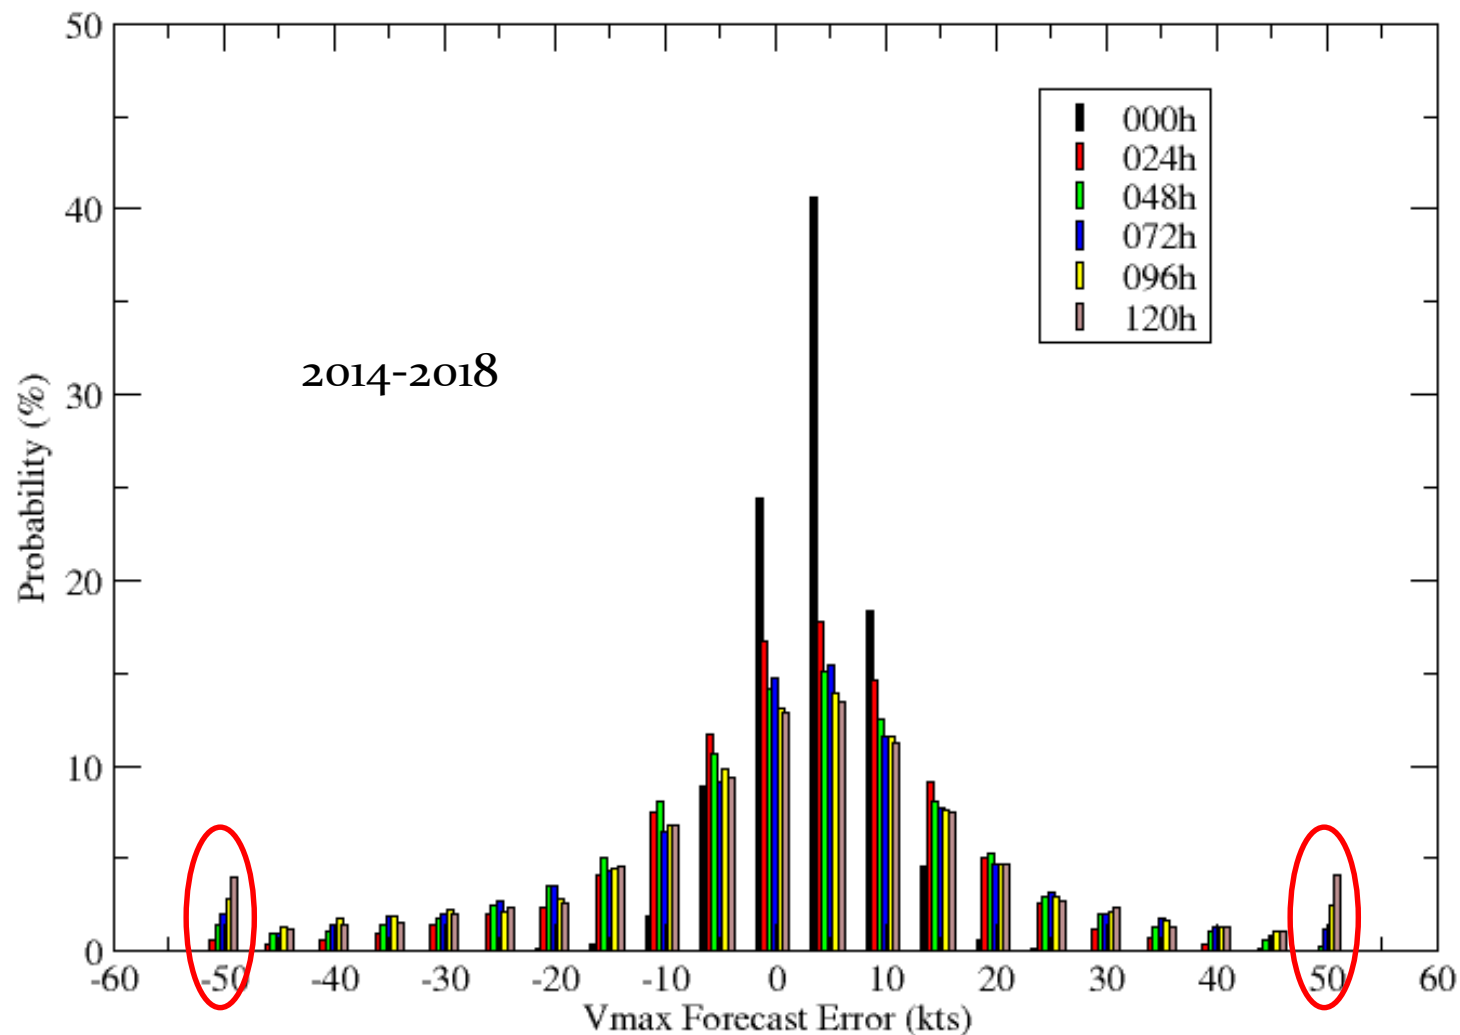

Small initial
perturbation

Under-disperse at all years

Track and Intensity Verification

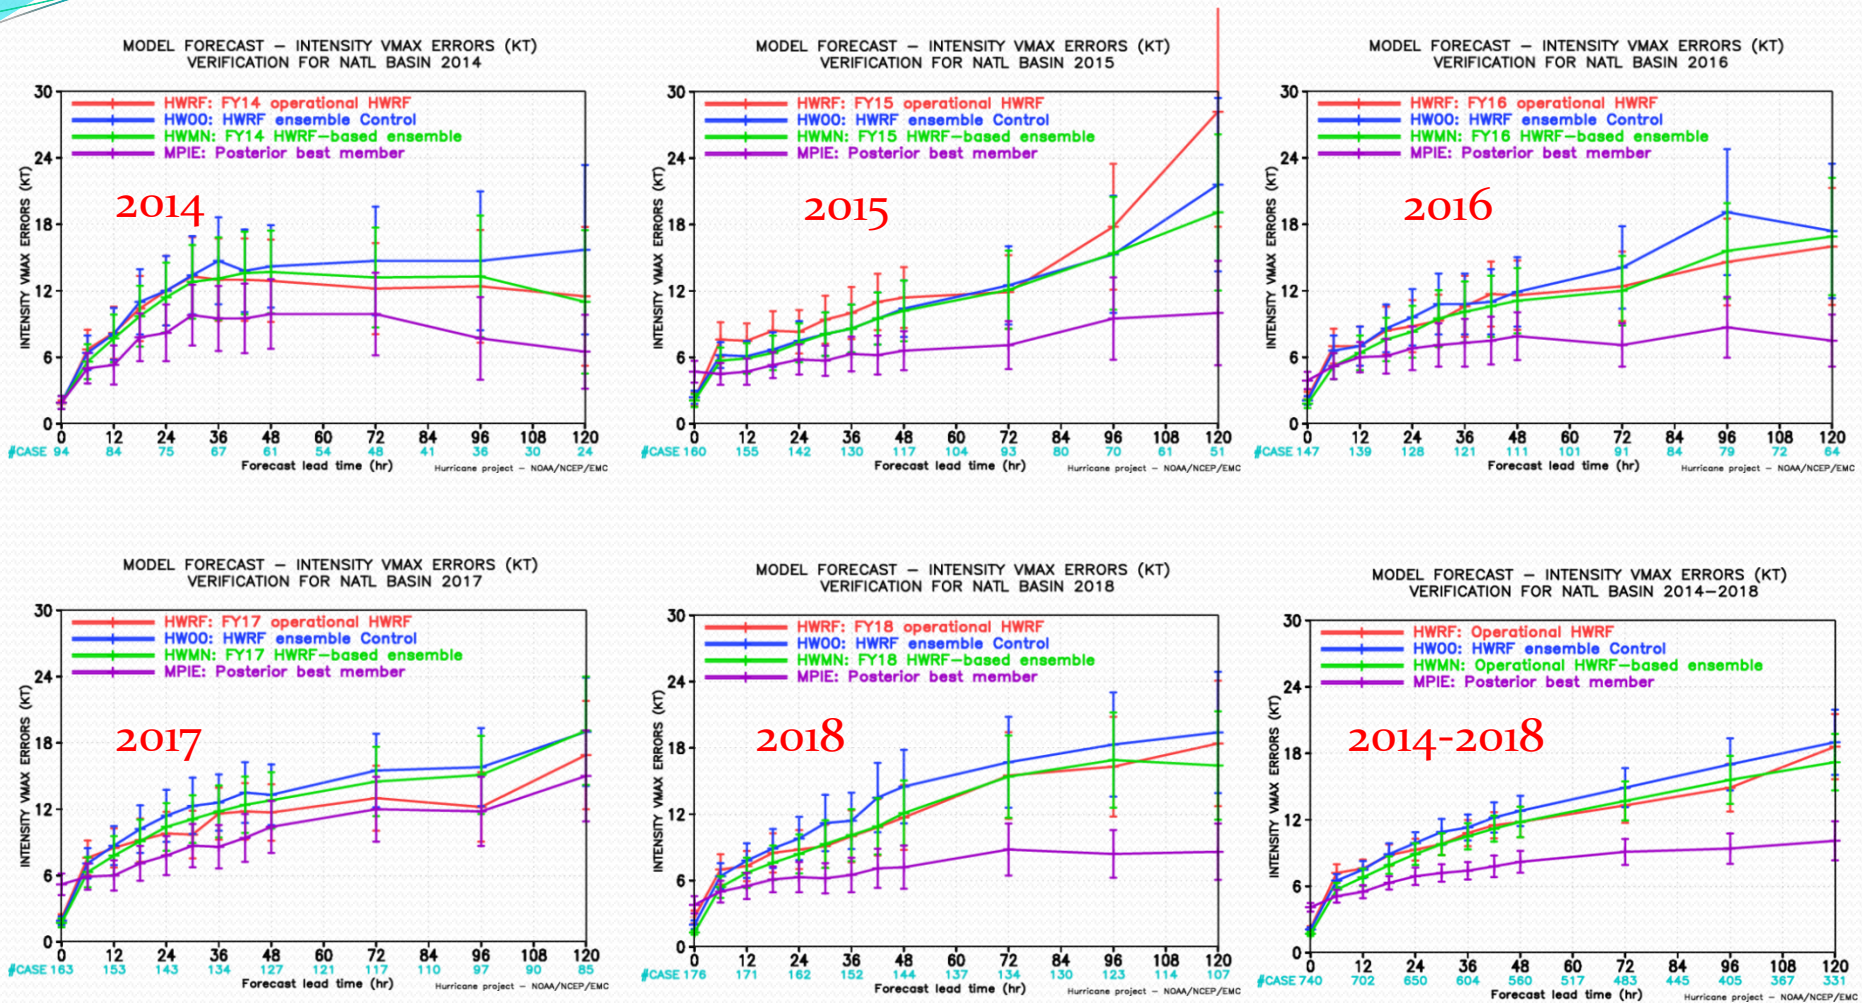

Track Verification for HWRF based Ensemble Prediction System

2014-2018

- Ensemble mean of HWRF-EPS (HWMN) always has lower track forecast than operational HWRF (HWRf)
- Posterior track forecasts (MPTE) have much lower track forecast error
- HWRF-EPS track forecast skills are comparable with operational HWRF at earlier forecast hours, and slightly degraded at later lead times due to lower resolution

Intensity Verification for HWRF based Ensemble Prediction System 2014-2018

- Ensemble mean of HWRF-EPS (HWMN) generally has lower intensity forecast than operational HWRF (HWRF)
- Posterior intensity forecast (MPTE) have much lower intensity forecast error
- HWRF-EPS intensity forecast skills are comparable with operational HWRF at all lead forecast hours

Track Forecast Skill Improvement of HWRF-EPS (Average over Sub-setting at 12h vs All ensemble members)

MODEL FORECAST – TRACK FORECAST SKILL (%) STATISTICS

VERIFICATION FOR NATL BASIN 2014–2018

~10% intensity improvement, HWMN vs HW00
Additional ~5-10% before 36h

Composite Tracks for Florence, 06L

MODEL FORECAST — TRACK ERRORS (NM)
STATISTICS FOR A SINGLE STORM — a1062018_FLORENCE

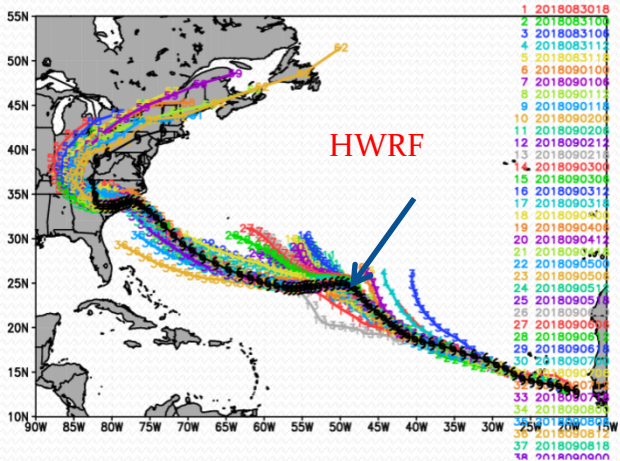

MODEL FORECAST — TRACK ERRORS (NM)
STATISTICS FOR A SINGLE STORM — a1062018_FLORENCE

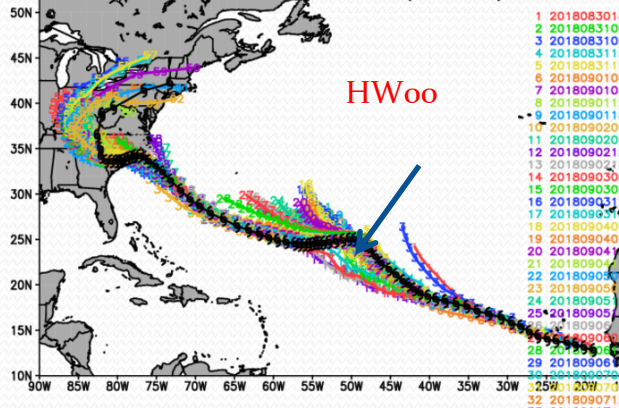

HWMN 2018 Parallel: TC Tracks
Storm: FLORENCE (06L) valid 2018090312

HWRf forecast: FLORENCE (a1062018)

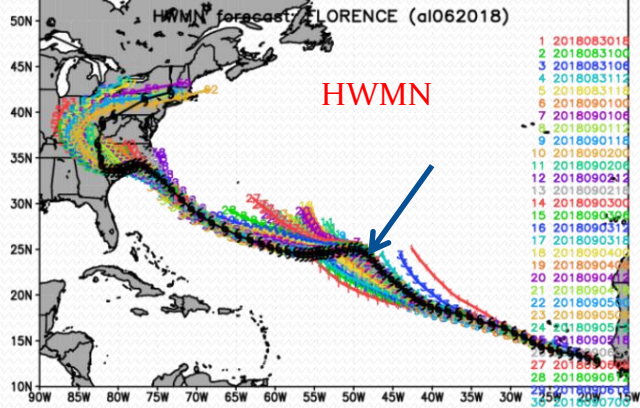

HWRf forecast: FLORENCE (a1062018)

HWRf forecast: FLORENCE (a1062018)

HWMN forecast: FLORENCE (a1062018)

1. All three systems missed westward turning point;
2. HWoo/HWMN have southward track bias following GEFS.

Composite Intensities for Florence o6L

MODEL FORECAST – INTENSITY VMAX ERRORS (KT)
STATISTICS FOR A SINGLE STORM – aI062018_FLORENCE

MODEL FORECAST – INTENSITY VMAX ERRORS (KT)
STATISTICS FOR A SINGLE STORM – aI062018_FLORENCE

HWRf forecast: FLORENCE (aI062018)
Maximum 10-m wind time series

HW00 forecast: FLORENCE (aI062018)
Maximum 10-m wind time series

HWMN forecast: FLORENCE (aI062018)
Maximum 10-m wind time series

Larger Ensemble Spread indicates larger Forecast Errors

HWMN Parallel: TC intensity Vmax

Storm: NINE (09L) INIT 2018090800

HWMN 2018 Parallel: TC Intensity Vmax

Storm: NINE (09L) valid 2018090800

HWMN Parallel: TC intensity Pmin

Storm: NINE (09L) INIT 2018090800

HWMN 2018 Parallel: TC Intensity Pmin

Storm: NINE (09L) valid 2018090800

Smaller Ensemble Spread indicates Smaller Forecast Errors

RI Probability Forecast from HWRF-EPS

Florence 06L

$$P_{RI} = N_{RI} / N_{total}$$

N_{RI} is the max No of ensemble members that predicted RI event in 96h;

N_{total} equals 20, the total No. of ensemble numbers.

Michael 14L

Concluding Remarks

- The statistical features of HWRF-EPS is evaluated
 - configured that each ensemble member has equal probability to be closest to the observed intensity and storm position
 - Ensemble spread is under-dispersed
 - Predicted Vmax is generally Gaussian distributed, except for relatively larger PDF at both ends
 - Cases of large Vmax forecast errors are investigated, and found 3 possible reasons: a). Rapid intensity, b). large track forecast errors; c). and model physics
- HWRF-EPS produces lower track/intensity forecast errors, compared to its deterministic control run at NATL basin for 2014-2018 hurricane seasons
- HWRF-EPS intensity forecasts have smaller errors compared to the operational HWRF even with lower resolutions and no data assimilation
- HWRF-EPS track forecast is still behind the operational HWRF (partially followed its parent model, GEFS)
- Assuming obs. At 12h is known, Sub-set of ensemble mean method provides further improvements on top of ensemble mean of all members
- HWRF-EPS demonstrated its capable of statistically predicting hurricane RI event.

Thank You!
